#### Lecture outline

- Support vector machines
- Boosting

• Find a linear hyperplane (decision boundary) that will separate the data

• One Possible Solution

• Another possible solution

• Other possible solutions

- Which one is better? B1 or B2?
- How do you define better?

• Find hyperplane maximizes the margin => B1 is better than B2

# Support Vector Machines • We want to maximize: $\operatorname{Margin}_{\operatorname{Margin}} = \frac{2}{||w||^2} \frac{2}{||w||^2}$ – Which is equivalent to minimizing: $L(\overline{w}) = \frac{||w||^2}{2}$

- But subjected to the following constraints:

$$f(\vec{x}_i) = \begin{cases} 1 & \text{if } \vec{w} \bullet \vec{x}_i + b \ge 1 \\ -1 & \text{if } \vec{w} \bullet \vec{x}_i + b \le -1 \end{cases}$$

This is a constrained optimization problem

 Numerical approaches to solve it (e.g., quadratic programming)

• What if the problem is not linearly separable?

- What if the problem is not linearly separable?
   Introduce slack variables
  - Need to minimize:  $L(w) = \frac{||\vec{w}||^2}{2} + C\left(\sum_{i=1}^N \xi_i^k\right)$ • Subject to:

$$f(\vec{x}_i) = \begin{cases} 1 & \text{if } \vec{w} \bullet \vec{x}_i + b \ge 1 - \xi_i \\ -1 & \text{if } \vec{w} \bullet \vec{x}_i + b \le -1 + \xi_i \end{cases}$$

#### Nonlinear Support Vector Machines

• What if decision boundary is not linear?

#### Nonlinear Support Vector Machines

• Transform data into higher dimensional space

## Ensemble Methods

- Construct a set of classifiers from the training data
- Predict class label of previously unseen records by aggregating predictions made by multiple classifiers

# Why does it work?

- Suppose there are 25 base classifiers
  - Each classifier has error rate,  $\epsilon = 0.35$
  - -Assume classifiers are independent
  - Probability that the ensemble classifier makes a wrong prediction:

$$\sum_{i=13}^{25} \epsilon^i (1-\epsilon)^{25-i} = 0.06$$

# Examples of Ensemble Methods

- How to generate an ensemble of classifiers?
  - Bagging
  - Boosting

# Bagging

• Sampling with replacement

Original Data	1	2	3	4	5	6	7	8	9	10
Bagging (Round 1)	7	8	10	8	2	5	10	10	5	9
Bagging (Round 2)	1	4	9	1	2	3	2	7	3	2
Bagging (Round 3)	1	8	5	10	5	5	9	6	3	7

- Build classifier on each bootstrap sample
- Each sample has probability 1-(1 1/n)<sup>n</sup> of being selected

# Boosting

- An iterative procedure to adaptively change distribution of training data by focusing more on previously misclassified records
  - Initially, all N records are assigned equal weights
  - Unlike bagging, weights may change at the end of boosting round

# Boosting

- Records that are wrongly classified will have their weights increased
- Records that are classified correctly will have their weights decreased

- Example 4 is hard to classify
- Its weight is increased, therefore it is more likely to be chosen again in subsequent rounds

#### Example: AdaBoost

- Base classifiers: C<sub>1</sub>, C<sub>2</sub>, ..., C<sub>T</sub>
- Data pairs: (x<sub>i</sub>,y<sub>i</sub>)
- Error rate:

$$\epsilon_i = \frac{1}{N} \sum_{j=1}^N w_j \delta\left(C_i(x_j) \neq y_j\right)$$

• Importance of a classifier:

$$\alpha_i = \frac{1}{2} \log \left( \frac{1 - \epsilon_i}{\epsilon_i} \right)$$

#### Example: AdaBoost

• Classification:

$$C^* = \arg\max_{y} \sum_{j=1}^{T} \alpha_j \delta\left(C_j(x) = y\right)$$

• Weight update for every iteration t and classifier j :

$$w_i^{(t+1)} = \frac{w_i^{(t)}}{Z_t} \begin{cases} \exp^{-\alpha_j} & \text{if } C_j(x_i) = y_i \\ \exp^{\alpha_j} & \text{if } C_j(x_i) \neq y_i \end{cases}$$

where  $Z_i$  is the normalization factor

 If any intermediate rounds produce error rate higher than 50%, the weights are reverted back to 1/n
